6
7

8 This application claims the benefit of U.S. Provisional
9 Application Number 60/427,918, filed 20 November 2002.
10
11

12 Field of the Invention
13

14 This invention relates generally to the field of optical
15 modules. In particular, the present invention relates to
16 improved digital diagnostic integrated circuits for use in
17 optical transceiver modules.
18
19

20 Background of the Invention
21

22 Fiber optics are increasingly used for transmitting voice
23 and data signals. As a transmission medium, light provides a
24 number of advantages over traditional electrical communication
25 techniques. For example, light signals allow for extremely
26 high transmission rates and very high bandwidth capabilities.

1 Also, light signals, when transmitted by optical fibers, are
2 resistant to electro-magnetic interferences that would
3 otherwise interfere with electrical signals. Light, when
4 transmitted by optical fibers, also provides a more secure
5 signal because it doesn't allow portions of the signal to
6 escape from the fiber optic cable as can occur with electrical
7 signals in wire-based systems. Light also can be conducted
8 over greater distances without the signal loss typically
9 associated with electrical signals on copper wire.

10
11 While optical communications provide a number of
12 advantages, the use of light as a transmission medium presents
13 a number of implementation challenges. In particular, the data
14 carried by light signal must be converted to an electrical
15 format when received by a device, such as a network switch.
16 Conversely, when data is transmitted to the optical network, it
17 must be converted from an electronic signal to a light signal.
18 A number of protocols define the conversion of electrical
19 signals to optical signals and the transmission of those
20 optical signals, including the ANSI Fiber Channel (FC) protocol
21 and the SFF-8472 standard. The FC protocol is typically
22 implemented using a transceiver module at both ends of a fiber
23 optic cable. Each transceiver module typically contains a
24 laser transmitter circuit capable of converting electrical
25 signals to optical signals, and an optical receiver capable of
26 converting received optical signals back into electrical

1 signals. Typically, a transceiver module is electrically
2 interfaced with a host device, such as a host computer,
3 switching hub, network router, switch box, computer I/O and the
4 like, via a compatible connection port.

5
6 A problem with these protocols is that they are often
7 revised. As a result, it generally becomes necessary to
8 upgrade the existing digital diagnostic integrated circuits
9 within the fiber optic module each time the protocols are
10 revised. Thus, it would be highly advantageous to provide a
11 fiber optic transceiver module which can be easily upgraded
12 with changes to the standard.

13
14 It would be highly advantageous, therefore, to remedy the
15 foregoing and other deficiencies inherent in the prior art.

16
17 Accordingly, it is an object the present invention to
18 provide new and improved optical transceiver modules.

19
20 Another object of the present invention is to provide new
21 and improved optical transceiver modules with improved digital
22 diagnostic integrated circuits.

1 Another object of the present invention is to provide new
2 and improved optical transceiver modules that are easily
3 upgraded with changes to the standard.

4

5 Another object of the present invention is to provide new
6 and improved optical transceiver modules that improve the
7 fabrication efficiency and manufacturing capabilities of
8 optoelectronic modules.

9

10 A further object of the present invention is to provide
11 new and improved methods of use of the optical transceiver
12 modules.

Summary of the Invention

Briefly, to achieve the desired objects of the instant invention in accordance with a preferred embodiment thereof, an optical transceiver module is disclosed with improved digital diagnostic integrated circuits. The optical transceiver includes an electrical-to-optical transmitter and an optical-to-electrical receiver each coupled to a digital diagnostic integrated circuit. A bi-directional 2-wire controls interface is provided and a microcontroller couples the digital diagnostic integrated circuit to the control interface. Various methods are described for using the microcontroller to incorporate changes or diagnostic functions in the digital diagnostic integrated circuit.

Desired objects of the instant invention are further realized in a method of controlling optical transceiver modules with improved digital diagnostic integrated circuits including the step of providing an optical transceiver module coupled to a digital diagnostic integrated circuit, an control interface, and a microcontroller coupling the digital diagnostic integrated circuit to the control interface. The method further includes the step of using the microcontroller to map addresses of IC's in the digital diagnostic integrated circuit for improved utilization of the IC's.

Desired objects of the instant invention are further realized in another method of controlling optical transceiver modules with improved digital diagnostic integrated circuits including the step of providing an optical transceiver module coupled to a digital diagnostic integrated circuit, a control interface, and a microcontroller coupling the digital diagnostic integrated circuit to the control interface. This method further includes the step of using the microcontroller to add diagnostic functions of the optical transceiver module and components in the optical transceiver module to the digital diagnostic integrated circuit. Some diagnostic functions that may be added include mapping registers in the digital diagnostic integrated circuit to different locations, adding flags, adding interrupt functions, and implementing password functions. Still another diagnostic function that may be added by the microcontroller includes modifying a register based interface to implement a command type interface.

1 Brief Description of the Drawings

2
3 The foregoing and further and more specific objects and
4 advantages of the instant invention will become readily
5 apparent to those skilled in the art from the following
6 detailed description of a preferred embodiment thereof taken in
7 conjunction with the drawings, in which:

8
9 FIG. 1 is a simplified block diagram of an optical
10 transceiver for a fiber optic module; and

11
12 FIG. 2 is a simplified block diagram of a programmable
13 optical transceiver for an optical module.

Detailed Description of the Drawings

Turning now to FIG. 1, a simplified block diagram of an optical transceiver 5, illustrates functions typically performed in a fiber optic module. Transceiver 5 is provided for purposes of explanation of functions and not as a prior art device. It will be understood, however, that the functions of optical transceiver 5 can be performed in other types of optoelectronic modules wherein it is desired to convert an optical signal to an electrical signal or vice versa. The transceiver illustrated in FIG. 1 represents a standard small form factor 8472 (hereinafter referred to as "SFF-8472"), Revision 9.0 digital diagnostic solution. However, it will be understood that the illustration of SFF-8472 in this embodiment is for illustrative purposes only and that other standards could be used. These fiber optic modules are typically designed for single mode operation up to 2.5 Gbps. Further, these modules typically operate at a nominal wavelength of 1300 nm using a direct modulated Fabry Perot (FP) or Distributed Feedback (DFB) laser, depending on the implementation.

The SFF-8472 specification includes the ability for a transceiver to sense key power characteristics including average laser diode (transmit) current, and average modulated input and output optical power. Further, SFF-8472 compliant transceivers are capable of sensing both supply voltage and

1 transceiver temperature, which is particularly important when
2 systems are exposed to extreme environmental conditions.

3

4 In FIG. 1, transceiver 5 includes a preamplifier 12 that
5 is electrically connected to a photodetector 11 which is
6 capable of detecting incident light 13. Incident light 13 can
7 be, for example, light generated from an optical fiber (not
8 shown) or the like, wherein it is desired to convert light 13
9 into an electrical signal. Preamplifier 12 is electrically
10 connected to a limiting amplifier 10 which behaves as a current
11 limiter. Limiting amplifier 10 has outputs DATA⁺ and DATA⁻
12 which are capable of outputting electrical data signals to
13 associated electronic circuitry (not shown). Similar
14 electrical data signals are applied to inputs DATA⁺ and DATA⁻ of
15 a laser driver 16 from the associated electronic circuitry. It
16 will be understood that the electrical signals on inputs and
17 outputs labeled DATA⁺ and DATA⁻ are the signals being
18 communicated between separated destinations and while referred
19 to herein as "data" may include any form of information that
20 can be transmitted by light waves. Limiting amplifier 10 is
21 electrically connected to a digital diagnostic integrated
22 circuit (hereinafter referred to as "DDIC") 14 which can
23 include, for example, a D51852 or D51858 integrated circuit
24 chip. The operation of DDIC 14 will be discussed in more
25 detail below.

1 DDIC 14 is electrically connected to a 2-wire control bus
2 by way of a control interface, which will also be discussed in
3 more detail below. Further, DDIC 14 is electrically connected
4 to laser driver 16. Laser driver 16 is electrically connected
5 to a light emitting device 17 which is capable of emitting
6 light 19 to, for example, an optical fiber (not shown) or a
7 similar optoelectronic element. Further, DDIC 14 is
8 electrically connected to a digital potentiometer 20, by way of
9 a control interface, and digital potentiometer 20 is also
10 electrically connected to laser driver 16. However, it will be
11 understood that digital potentiometer 20 is optional, but is
12 included in this embodiment for illustrative purposes. As
13 mentioned previously, laser driver 16 receives electrical data
14 signals from the associated electronic circuitry on electrical
15 inputs DATA⁺ and DATA⁻.

16
17 The control interface is capable of providing a
18 communication path with optical amplifiers. The control
19 interface was developed as a simple bi-directional 2-wire bus
20 for efficient inter-IC control. At present, the control
21 interface bus, for example, includes more than 150 CMOS and
22 bipolar control interface bus compatible types for performing
23 communication functions between intelligent control devices
24 (e.g. microcontrollers), general-purpose circuits (e.g. LCD
25 drivers, remote I/O ports, memories) and application-oriented
26 circuits (e.g. digital tuning and signal processing circuits

1 for radio and video systems). Control interface compatible
2 devices usually incorporate an on-chip interface which allows
3 them to communicate directly with each other via the control
4 interface. This design concept substantially solves the many
5 interfacing problems encountered when designing digital control
6 circuits.

7
8 DDIC 14 provides optical transceiver 5 Enhanced Digital
9 Diagnostics capability by using ICs (e.g. registers, control
10 chips, optical monitoring chips, etc.) that enables end users
11 to remotely monitor key module parameters to ensure system
12 compatibility and operation within required operating ranges.
13 Along with the standard module identification information, DDIC
14 14 allows Enhanced Diagnostics, which monitor parameters such
15 as laser condition, optical power, internal temperature, and
16 supply voltage. Data can be continually updated to provide
17 users real-time updates of module condition and link stability.
18 The optical monitoring chips included in DDIC 14 are designed
19 to offer complete Enhanced Diagnostics capability over the
20 standard Small Form Factor pluggable (hereinafter referred to
21 as "SFP") electrical interface. The ICs' small size makes them
22 ideal for very dense packaging applications such as those in
23 SFP modules.

24
25 Further, digital diagnostic capabilities in each module
26 offer the ability to identify each optical module on the

1 system. For example, a chip that stores supplier information
2 is capable of allowing customers and end users to identify the
3 module supplier and confirm that it's a qualified source. In
4 particular, company-specific information can be stored in
5 registers that identify the company. Further, the registers
6 can store product information so that users can query the
7 device to make sure it's the right one for the intended
8 application.

9
10 DDIC 14 can also feature enhanced diagnostics capabilities
11 that allow users to check the performance of optical
12 components. For example, there can be warning and alarm
13 settings in the registers that automatically alert the end
14 users if parameters go beyond a predetermined level. One such
15 parameter is the laser bias current. If the laser bias current
16 is exceedingly high, it may mean the laser is close to end-of-
17 life. Another such parameter is the internal module
18 temperature. If the internal module temperature is too high,
19 then it may imply that the ambient temperature in the system
20 has gone beyond specified limits. Still another parameter is
21 the laser output power. If output power is too high, then it
22 can indicate that laser safety compliance is at risk. Another
23 parameter is the supply voltage level. If the supply voltage
24 level is too low, then the module performance could become
25 unreliable.

1 Turn now to FIG. 2 which illustrates a schematic of an
2 improved optical transceiver 7 used to provide electronic
3 control functions in a fiber optic module and to a digital
4 diagnostic IC. Transceiver 7 illustrated in FIG. 2 is for a
5 standard SFF-8472, Revision 9.0 digital diagnostic solution
6 similar to that illustrated in FIG. 1 (i.e. optical transceiver
7 5). However, it will be understood that the illustration of
8 this standard in this embodiment (i.e. optical transceiver 7)
9 is for illustrative purposes only and that other standards
10 could be used. It will be noted that in FIG. 2, components
11 performing functions similar to those illustrated in FIG. 1 are
12 labeled by adding a one to each element number.

13
14 In FIG. 2, a preamplifier 112 is electrically connected to
15 a photodetector 111 which is capable of detecting incident
16 light 113. Incident light 113 can be, for example, light
17 generated from an optical fiber (not shown) or the like wherein
18 it is desirable to convert light 113 into an electrical signal.
19 Preamplifier 112 is electrically connected to a limiting
20 amplifier 110 which behaves as a current limiter. Limiting
21 amplifier 110 has outputs DATA⁺ and DATA⁻ which are capable of
22 outputting electrical data signals to associated electronic
23 circuitry (not shown). Further, limiting amplifier 110 is
24 electrically connected to a digital diagnostic integrated
25 circuit (hereinafter referred to as "DDIC") 114 which can

1 include, for example, a D51852 or D51858 integrated circuit
2 chip.

3
4 DDIC 114 is electrically connected to a microcontroller
5 122 and to a laser driver 116. Laser driver 116 is
6 electrically connected to a light emitting device 117 which is
7 capable of emitting light 119 to, for example, an optical fiber
8 (not shown) or a similar optoelectronic element.
9 Microcontroller 122 is electrically connected to a control
10 interface and to a digital potentiometer 120, which is also
11 electrically connected to laser driver 116. Here it will be
12 understood that microcontroller 122 may include, for example,
13 any of the well known microprocessors or similar devices
14 capable of storing programs, providing control signals, and
15 being controlled with remotely generated control signals.
16 Generally, digital potentiometer 120, or similar control
17 device, is employed to control driving current to light
18 emitting device 117, and preferably is used to ensure a
19 constant drive over the life of light emitting device 117. It
20 should be understood that digital potentiometer 120 is
21 optional, but is included in this embodiment for illustrative
22 purposes. Laser driver 116 is capable of receiving electrical
23 data signals from the associated electronic circuitry on inputs
24 DATA⁺ and DATA⁻. As stated above, it should be understood that
25 the electrical signals on inputs and outputs labeled DATA⁺ and
26 DATA⁻ are the signals being communicated between separated

1 destinations and while referred to herein as "data" may include
2 any form of information that can be transmitted by light waves.

3
4 The use of microcontroller 122 within optical transceiver
5 7 allows the ability to fix changes of diagnostic IC compliance
6 in two wire interface standards like SFF-8472. In particular,
7 microcontroller 122 allows existing digital diagnostic IC's
8 (e.g. those IC's included in DDIC 114) to effectively be
9 upgraded to compliance due to revisions in the standard. For
10 example, microcontroller 122 can be used to map the address of
11 the control interface to better utilize the IC's in DDIC 114.
12 Further, microcontroller 122 can be used to fix addressing
13 requirement changes through updates to the standard without
14 waiting for suitably fixed DDIC's.

15
16 In addition, microcontroller 122 can allow diagnostics
17 functions pertinent to particular requirements. Further,
18 microcontroller 122 can be used to interrupt the flow of data
19 from the control interface to modify the behavior of
20 transceiver 7 as measured from the control interface. Other
21 uses of microcontroller 122 include, but are not limited to,
22 using microcontroller 122 to map registers in diagnostic IC to
23 effectively other locations, add flags and interrupt functions
24 to transceiver 7, implement password functions, and/or modify
25 the register based interface to implement a command type
26 interface. Thus, microcontroller 122 allows optical

1 transceiver 7 to operate independently to revisions in the
2 standard.

3
4 Thus, new and improved optical modules are disclosed with
5 improved digital diagnostic integrated circuits. The new and
6 improved optical modules are easily upgraded with changes to
7 the standard and substantially improve fabrication efficiency
8 and manufacturing capabilities of optoelectronic modules.
9 Further, new and improved uses of the new optical modules are
10 disclosed.

11
12 Various changes and modifications to the embodiments
13 herein chosen for purposes of illustration will readily occur
14 to those skilled in the art. To the extent that such
15 modifications and variations do not depart from the spirit of
16 the invention, they are intended to be included within the
17 scope thereof which is assessed only by a fair interpretation
18 of the following claims.

19
20 Having fully described the invention in such clear and
21 concise terms as to enable those skilled in the art to
22 understand and practice the same, the invention claimed is:
